Faculty of Geology, Kraków, Poland

Abstract

This work presents the results of microbiological investigations carried out in the Polish part of the Muskau Arch. In this abandoned lignite mining area highly acidified Fe-rich waters have been formed as a result of sulphide oxidation. Microbiological tests have shown that all studied groups of microorganisms exhibit both time and spatial variability. The most common group of microorganisms are bacteria *Galonella sp.*

Keywords: AMD environment, the Muskau Arch, microbiological variability

1. INTRODUCTION

The Muskau Arch is a large glacitectonic belt formed mainly during the Saale glaciation. This horseshoe-shaped structure is open to the north (Fig. 1) and crosses the Polish-German border (from Brandenburg, via Saxony to the Lubuskie Province in Poland). Intense glacitectonics disturbances lifted Miocene lignite beds (as well as co-occurring sands and clays) towards the Earth's surface - making them much easier to exploitation carried out both by underground and open pit methods.

The mining of these deposits was active till the end of the 70-ties of the 20th century. Abandoned excavations have been recently filled with water, forming

about 110 reservoirs in the so called *Anthropogenic Lake District*. Many of these lakes, especially in the Łęknica Region, are of the acidotrophic type, characterized by low and very low pH values (usually below 4.0). This is an effect of the oxidation of sulphide-containing lignite leading to the generation of abundant quantities of sulphuric acid. Numerous ochreous precipitates occur in this area, as a consequence of iron oxidation and hydrolysis in the presence of microorganisms. The main objective of the study is the confirmation of the presence of iron-oxidizing bacteria in the waters of *Anthropogenic Lake District*, which would justify the role of their metabolism in the ferruginous precipitates formation. The quantitative seasonal variability of their population sizes, depending on changing ambient conditions as temperature, precipitation, insolation etc., have also been estimated.

2. MATERIALS AND METHODS

The fieldwork started in July 2009 and ended in September 2010. Water samples from five localities (Fig. 2) were monthly collected and subjected to both microbiological and chemical analyses.

Such parameters as temperature, electrolytic conductivity, redox potential and pH of the waters were measured *in situ*. Then the samples were filtered using 0.22 µm syringe filters and stabilized with HNO₃. The cation concentrations were estimated using ICP-MS (Ca, Mg, Mn, Al, As) and FES (Na, K). Total Fe as well as selected anions (NO₂⁻, NO₃⁻, SO₄²⁻) were measured by VIS spectrometry and Cl⁻ by titration with AgNO₃.

The results of the chemical analysis have already been published by the authors [1-4].

Chosen groups of microorganisms were incubated on Petri dishes or in tubes and then characterized qualitatively and quantitatively after a specific time of incubation. The optimal incubation time and temperature were established as follows:

- 24 hours and 37°C for mesophilic bacteria,
- 72 hours and about 23°C for psychrophilic bacteria,
- about 10 days and 28°C for *Heterotrophic Ferruginous Bacteria*, *Acidithiobacillus ferrooxidans*, filamentous bacteria of the genera *Leptothrix* sp., *Gallionella* sp. and fungi.

The growth media for these groups of microorganisms were as follows:

- psychro- and mesophilic bacteria: MPA medium [9],
- *Heterotrophic Ferruginous Bacteria*: medium based on Winogradski receipt [7],
- *A. ferrooxidans*: 9K medium [8],
- *Fungi*: the Czapek-Dox medium [7],
- *Leptothrix* sp.: “Mulder - Van Veen” medium [9],
- *Gallionella* sp.: “Lieske” medium [7].

3. RESULTS AND DISCUSSION

The results show that the waters are rich in both auto- and heterotrophic microorganisms (Fig. 4, 5, Phot. 1). Their effect on water chemistry is immediate. It results from a change in their physical and chemical environment of the basic parameters such as pH and Eh.

The results of pH-Eh measurements as well as concentration of iron justify the presence of iron bacteria in the research area. These parameters are compatible

with the physicochemical conditions [6] essential for the existence and growth of so called iron bacteria (Fig. 3).

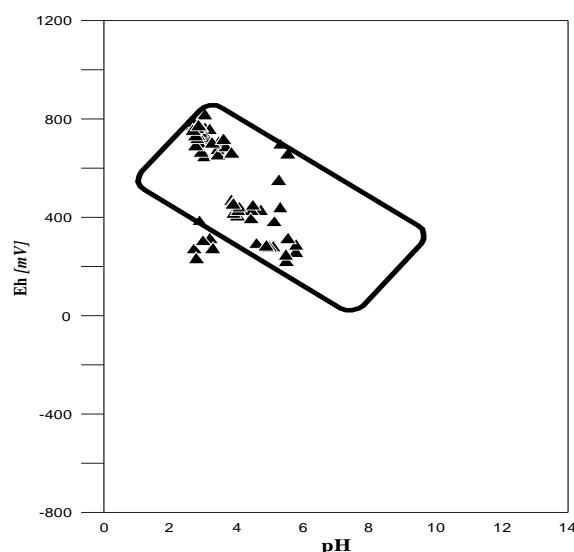

Fig. 3. A projection of pH and Eh values in the *Anthropogenic Lake District* waters. black rectangle - the conditions favouring the existence of ferruginous bacteria [6]

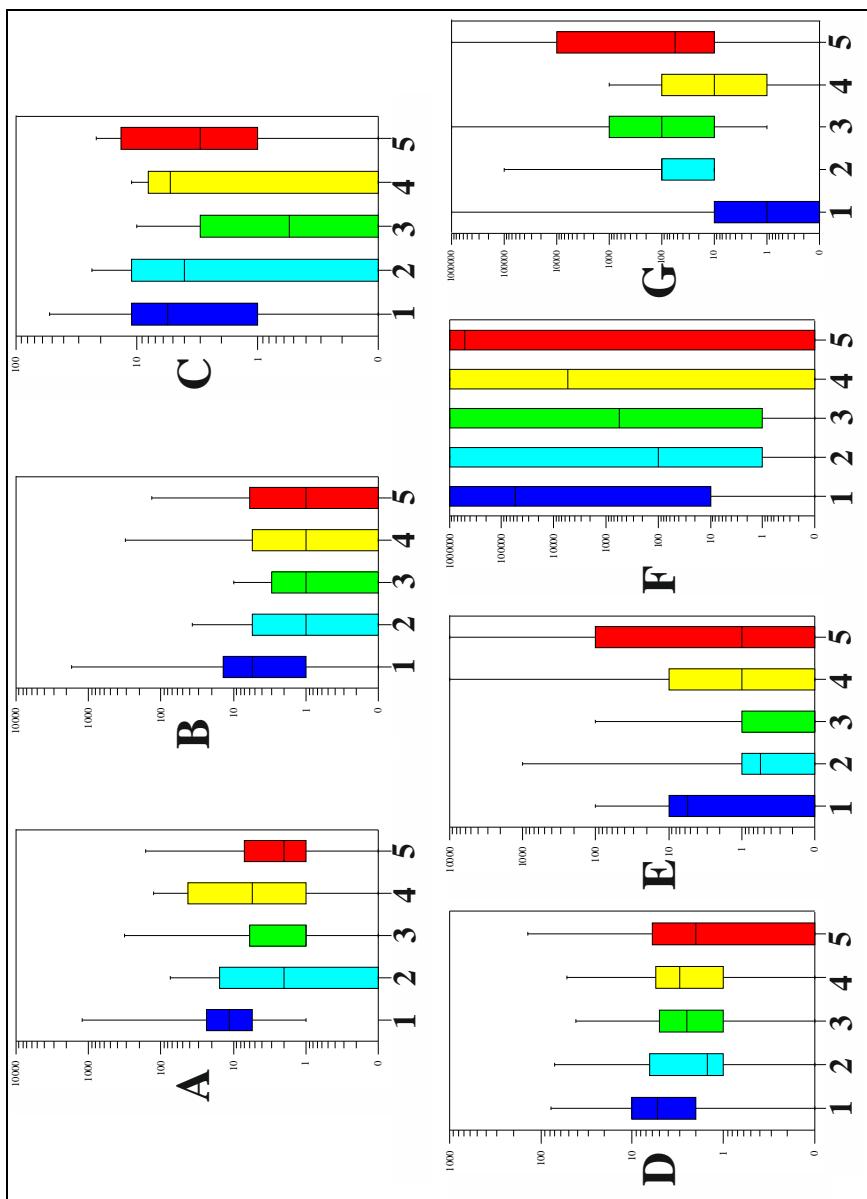

Fig. 4. An illustration of population sizes of microorganisms (measured as amounts of bacteria cells in 1 mL of the water). A - psychrophilic bacteria; B - mesophilic bacteria; C - fungi; D - *Leptothrix sp.*; E - *Heterotrophic Ferruginous Bacteria*; F - *Gallionella sp.*; G - *Acidithiobacillus ferrooxidans*; 1-5 - sampling points; 1 - "Wyciek źródłowy"; 2 - "Misa źródłowa I"; 3 - "Misa źródłowa II"; 4 - "Misa źródłowa III"; 5 - "Rozlewisko"

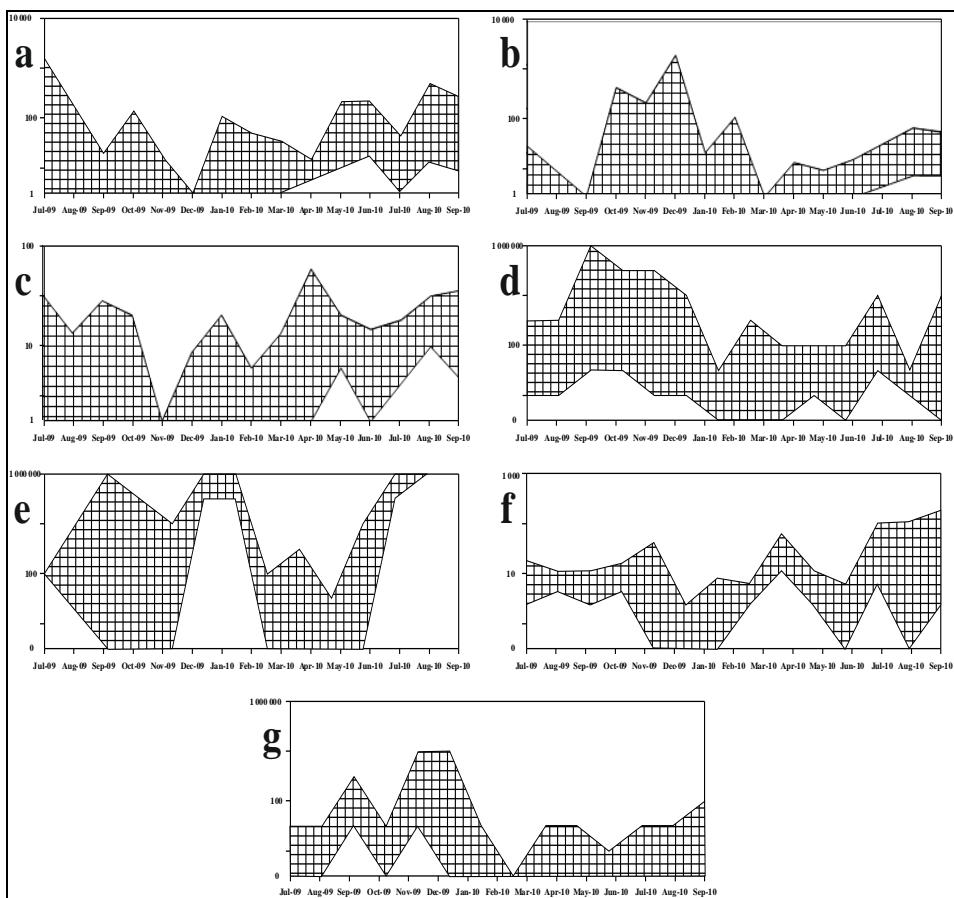

Fig. 5. Seasonal variations of the population sizes of selected groups of microorganisms (the crosshatched area shows the ranges of the values observed in different sampling points); a - psychrophilic bacteria; b - mesophilic bacteria; c - fungi; d - *Acidithiobacillus ferrooxidans*; e - *Galionella* sp.; f - *Leptothrix* sp.; g - *Heterotrophic Ferruginous Bacteria*

Microbiological analyses showed that the most numerous bacteria in *Anthropogenic Lake District* waters are filiform variety of *Galionella* sp. (Fig. 4 - 6). However, it is noteworthy that their population size did not correlate with measured ambient temperature. The explanation of this situation might be as follows: another abundant microorganism in this area is *Acidithiobacillus ferrooxidans*, which consumes the same nutrients. To win the “competition” these bacteria can even inhibit growth of their population. They are also more sensitive to temperature changes.

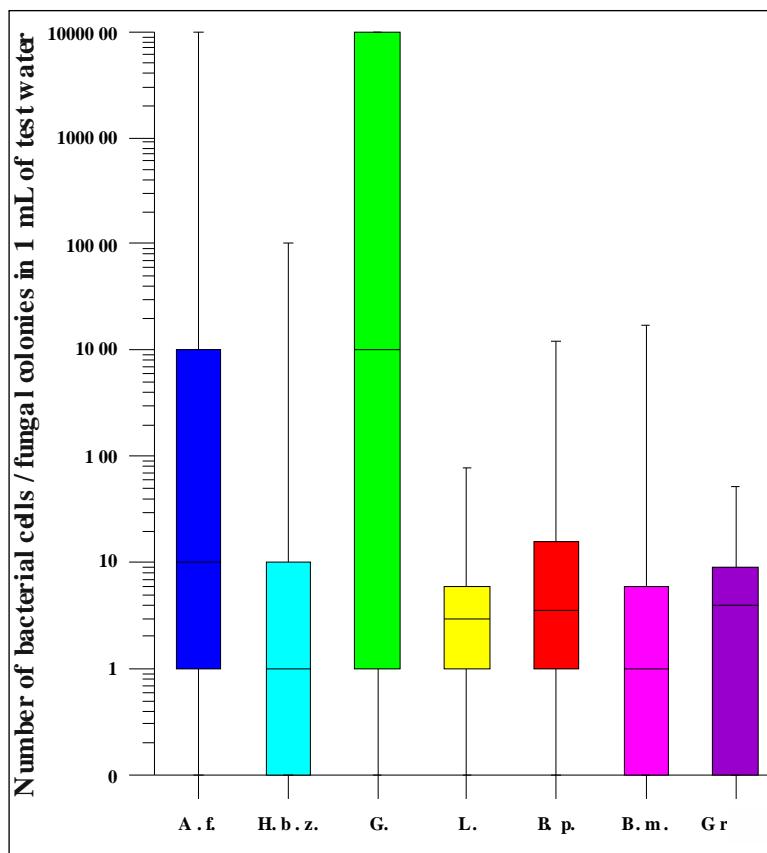

Fig. 6. Total population sizes (from all localities) of microorganisms. Explanations:
A. f - *Acidithiobacillus ferrooxidans*; HBZ - *Heterotrophic Ferruginous Bacteria*,
G. - *Galonella sp.*, L - *Leptothrix sp.*, B. p - psychrophilic bacteria,
B. m - mesophilic bacteria, Gr - fungi

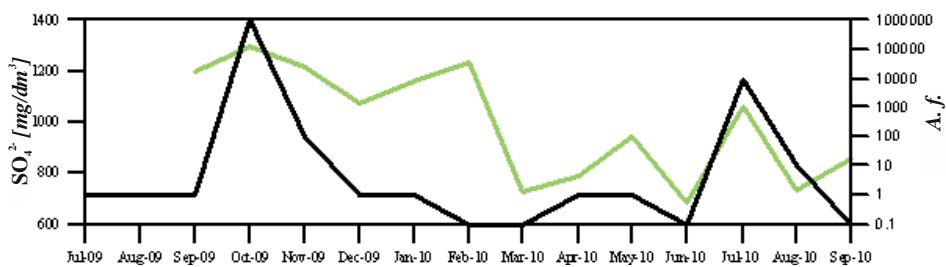

Fig. 7. The variability of sulphate concentration and the *Acidithiobacillus ferrooxidans* population size in the sampling point "Rozlewisko"

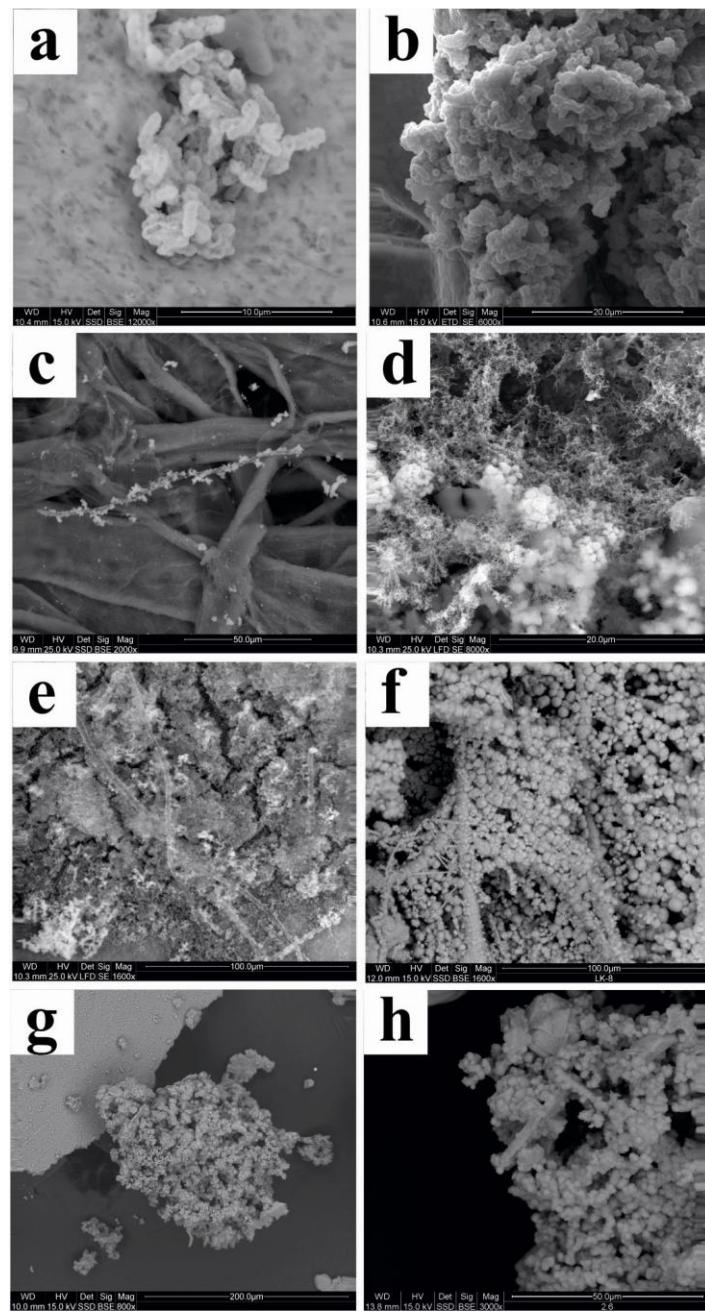

Photo 1. SEM images of isolated bacterial cultures; a, b - *Acidithiobacillus ferrooxidans*; c - f - *Galonella sp.*; g, h - *Heterotrophic Ferruginous Bacteria*

The performed analyses confirmed the impact of some microorganisms - mainly *Acidithiobacillus ferrooxidans* and *Heterotrophic Ferruginous Bacteria* on the processes of iron sulphide oxidation. This is reflected, in inter alia a strong positive correlation between the size of their populations and the sulphate concentration (Fig. 7).

On the basis of the results of this research another conclusion can be drawn - if we consider the population sizes of psychro- and mesophilic bacteria as well as fungi we can say that water in the tested sites exhibits good sanitary conditions. This is certainly true only in terms of microbiological conditions.

**WYNIKI BADAŃ MIKROBIOLOGICZNYCH PROWADZONYCH
W ZBIORNIKACH KWAŚNYCH WÓD KOPALNIANYCH W POLSKIEJ CZĘŚCI
ŁUKU MUŻAKOWA – NAJWIĘKSZYM TEGO TYPU ŚRODOWISKU W POLSCE**

S t r e s z c z e n i e

W rejonie Łuku Mużakowa prowadzona była eksploatacja m.in. węgla brunatnego. Działalność kopalń w tym rejonie trwała do końca lat 70. XX wieku. Po zakończeniu eksploatacji w obniżeniach terenu powstały liczne zbiorniki wodne, tworzące tzw. pojezierze antropogeniczne. W wyniku utleniania siarczków (głównie pirytu) występujące tutaj wody są bogate w żelazo oraz charakteryzują się bardzo niskim pH. W pracy przedstawiono wyniki badań mikrobiologicznych wykonywanych w polskiej części tej struktury geologicznej. Stwierdzono, że wszystkie badane grupy mikroorganizmów wykazują zmienność zarówno czasową (wynikającą z pór roku) jak i przestrzenną (wynikającą z miejsca pobrania próbki do badań). Wykazano, iż najliczniejszą grupą mikroorganizmów są nitkowate bakterie z rodzaju *Gallionella*. Stosunkowo liczne są ponadto bakterie *Acidithiobacillus ferrooxidans*. Ponieważ obie te grupy mikroorganizmów do swojego wzrostu potrzebują tych samych związków chemicznych ich populacje konkurują ze sobą – nawet kosztem ograniczenia tempa rozwoju populacji własnego gatunku.

Słowa kluczowe: środowisko AMD, Łuk Mużakowa, zmienność mikrobiologiczna
